Abstract

This report considers the security of smart contracts of the Nomis protocol. Our task is to find and describe security issues using the static-analysis tools Slither and Slitherin and help resolve them.

The work is financially covered by the Arbitrum Foundation grant.

Disclaimer

Current work does not give any warranties on the security of the code. It is not an audit or its replacement. Performing this scan, we focused on finding as many crucial issues as possible rather than making sure that the protocol was entirely secure. We always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contracts.

Summary

In this report, we described issues found in smart contracts of the Nomis protocol.

We scanned the codebase and manually rejected or verified all automated findings, revealing two relevant issues.

The developers fixed and commented on one issue.

The entire process is described in the section below.

Scan process

Under the Arbitrum Foundation grant, we researched and developed Arbitrum-specific detectors. They became publicly available with Slitherin v0.6.0 release.

Workflow

This work consisted of five stages:

- **1.** For the scan, we were provided with the Nomis project on a private GitHub repository, commit df15683c6e2f4f53dc79f196a84dd2e4f8c51f22.
- **2.** For the analysis of the protocol, we launched Slither v0.10.1 and Slitherin v0.6.0 on the provided codebase.
- **3.** One auditor manually checked (rejected or accepted) all findings reported by the tools. The second auditor verified this work. We shared all relevant issues with the protocol developers and answered their questions.
- **4.** The developers reviewed the findings, updated the code accordingly, and gave comments on issues. We reviewed the fixes and found no new issues.
- **5.** We prepared this final report summarizing all the issues and comments from the developers.

Issue categories

Within the confines of this work, we were looking for:

- · Arbitrum-specific problems;
- Standard vulnerabilities like re-entrancy, overflow, arbitrary calls, etc;
- Non-compliance with popular standards like ERC20 and ERC721;
- · Some access control problems;
- Integration issues with some popular DeFi protocols;
- A wide range of code quality and gas efficiency improvement opportunities.

This scan does not guarantee that these issues are not present in the codebase.

Discovered Issues

Uninitialized variable

In the NomisScore.sol contract, the _individualReward mapping is never initialized. However, its default values are used in setScore, claimReferralRewards, getClaimableReward functions without impacting on their logic, as when the _individualReward is equal to zero, the value of _referralReward is used instead. We recommend removing the _individualReward mapping to improve code quality and decrease gas consumption, or adding a function to modify the values of the individualReward mapping.

<u>Comment from the developers:</u> Yes, this bug exists in this version of the code. There is a function for modifying the <u>individualReward</u> values in the current version of the code.

External vs public

The <code>getWalletsByReferrerCode</code> and <code>initialize</code> functions of the <code>NomisScore</code> contract can be declared as <code>external</code>. Consider declaring functions as <code>external</code> instead of <code>public</code> when possible to improve code readability and optimize gas consumption.
